

## TIMING OF LATE QUATERNARY EARTHQUAKES ON THE HEBGEN LAKE FAULT BY COSMOGENIC CHLORINE-36 DATING OF BEDROCK FAULT SCARP

ZREDA, Marek, Department of Hydrology and Water Resources, University of Arizona, Tucson, AZ 85721, marek@hwr.arizona.edu; NOLLER, Jay S., Department of Geology, Vanderbilt University, Nashville, TN 37235.

Fault scarps along the Hebgen Lake fault, Montana, recorded multiple large paleoearthquakes, including the most recent earthquake in 1959. We used cosmogenic  $^{36}\text{Cl}$  in bedrock scarp faces exposed at the surface due to recurring faulting to determine ages of paleoearthquakes at Hebgen Lake. The technique measures how long the different, episodically offset parts of the scarp have been exposed to cosmic radiation.

Twenty-seven samples collected every 0.5 m from the bottom (0 m) to the top (12 m) of the scarp yielded the following exposure ages: 0.4 (for the 1959 scarp), 1.7, 2.6, 7.0, 20, 24 and 37 kyr (maximum age).

The data indicate two periods of heightened earthquake activity during which the displacement occurred: from 0 to 7 kyr ago and from 20 to 24 kyr ago, and two periods of quiescence: from 7 to 20 kyr and from 24 to 37 kyr. This temporal pattern suggests that the Hebgen Lake fault may be cyclic, with period of 15-20 kyr, presently in its active state. The average displacement rate during the two active periods is about 1 m/kyr, twice as high as that calculated over the entire geological history of the fault recorded in the scarp.

# Goal

**To determine the applicability of cosmogenic  $^{36}\text{Cl}$  to:**

**Dating of bedrock fault scarps**

**Measuring displacement rates**

Fault scarps along the Hebgen Lake fault, Montana, recorded multiple large paleoearthquakes, including the most recent earthquake in 1959. We used cosmogenic  $^{36}\text{Cl}$  in bedrock scarp faces exposed at the surface due to recurring faulting to determine ages of paleoearthquakes at Hebgen Lake. The technique measures how long the different, episodically offset parts of the scarp have been exposed to cosmic radiation. Twenty-seven samples collected every 0.5 m from the bottom (0 m) to the top (12 m) of the scarp yielded the following exposure ages: 0.4 (for the 1959 scarp), 1.7, 2.6, 7.0, 20, 24 and 37 kyr (maximum age). The data indicate two periods of heightening: from 0 to 7 kyr ago and from 20 to 24 kyr ago, and two periods of quiescence: from 7 to 20 kyr and from 24 to 37 kyr. This temporal pattern suggests that the Hebgen Lake fault may be cyclic, with a period of 15-20 kyr between active and inactive state. The average displacement rate during the two active periods is about 1 m/kyr, twice as high as that calculated over the entire geological history of the fault recorded in the scarp.

## Hebgen Lake fault scarp

Fault scarps along the Hebgen Lake fault, Montana, recorded multiple large paleoearthquakes, including the most recent earthquake in 1959. We used cosmogenic  $^{36}\text{Cl}$  in bedrock scarp faces exposed at the surface due to recurring faulting to determine ages of paleoearthquakes. We measured  $^{36}\text{Cl}$  concentrations at different, episodic intervals along the scarp face to determine how long the scarp face has been exposed to cosmic radiation. Twenty-seven samples were collected from the bottom (0 m) to the top (12 m) of the scarp face to determine age ranges: 0.4 kyr (for the 1959 earthquake) to 37 kyr (maximum age). The data indicate recent fault activity during the last 20 kyr and from 20 to 37 kyr ago. The Hebgen Lake fault may be cyclic, with period of 15-20 kyr, presently in its active state. The average displacement rate during the two active periods is about 1 m/kyr, twice as high as that calculated over the entire geological history of the fault recorded in the scarp.

## Scarp - close up

Fault scarps along the Hebgen Lake fault, Montana, recorded multiple large paleoearthquakes, including the most recent earthquake in 1959. We used cosmogenic  $^{36}\text{Cl}$  in bedrock scarp faces exposed at the surface due to re-exposure by earthquakes to determine ages of paleoearthquakes at Hebgen.  $^{36}\text{Cl}$  measures how long the scarp faces have been exposed to cosmic radiation.

Twenty-seven samples were collected from the bottom (0 m) to the top (12 m) of the scarp to determine exposure ages: 0.4 to 1.3 kyr (for the 1959 scarp), 1.3 to 37 kyr (maximum age). The data indicate two periods of earthquake activity during which the displacement occurred: one from 24 kyr ago and two periods from 7 to 20 kyr and from 24 to 37 kyr. This tem-plate suggests that the Hebgen Lake fault may be cyclic, with periods of activity presently in its active state. The average displacement rate during the two active periods is about 1 m/kyr, twice as high as that calculated over the entire geological history of the fault recorded in the scarp.

## Scarp - side view

Fault scarps along the Hebgen Lake fault, Montana, recorded multiple large paleoearthquakes, including the most recent earthquake in 1959. We used cosmogenic  $^{36}\text{Cl}$  in bedrock scarp faces exposed at the surface due to paleoearthquakes at Hebgen Lake to determine how long they have been exposed to cosmic radiation.

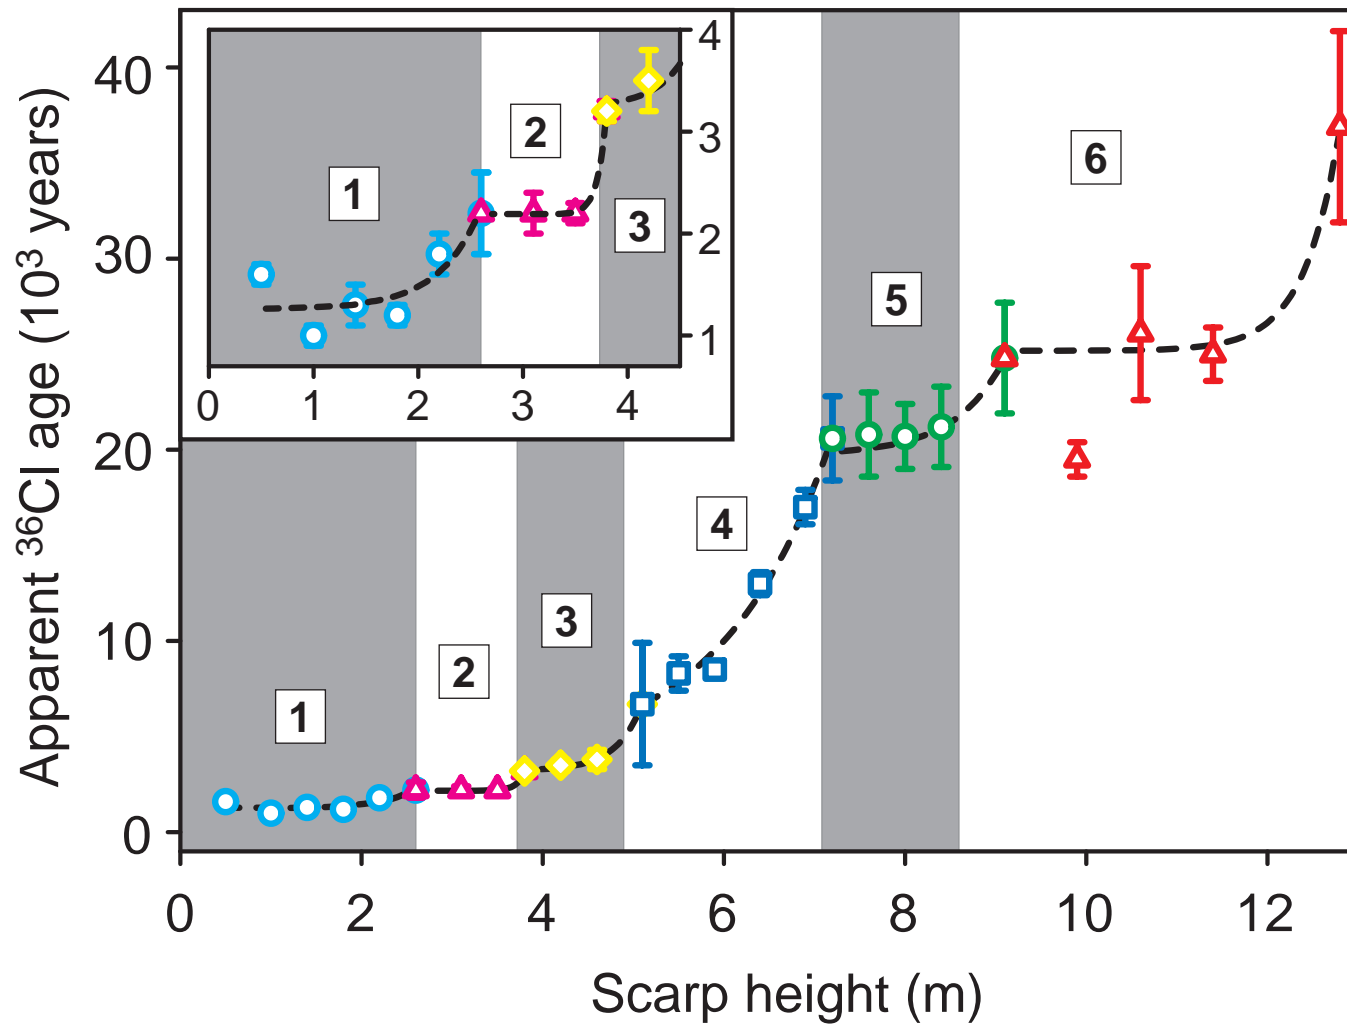

Twenty-seven samples were collected from the bottom (0 m) to the top (12 m) of the scarp to determine exposure ages: 0.4 to 7 kyr (maximum age). The data indicate two periods of earthquake activity during which the displacement was about 1 m/kyr, twice as fast as the average displacement rate of 0.5 m/kyr. This indicates that the Hebgen Lake fault may be cyclic, alternating between active and inactive states. The average displacement rate is about 1 m/kyr, twice as fast as the average displacement rate of 0.5 m/kyr over the entire geological history of the fault recorded in the scarp.

## Scarp - sampling

Fault scarps along the Hebgen Lake fault, Montana, recorded multiple large paleoearthquakes, including the most recent earthquake in 1959. We used cosmogenic  $^{36}\text{Cl}$  in bedrock scarp faces exposed at the surface due to recurring faulting to determine ages of paleoearthquake scarps. We sampled 20 different, epithermal scarp faces exposed to cosmic radiation. Twenty-seven samples were collected from the top (12 m) to the base (0 m) of the scarp. The ages: 0.4 kyr (minimum age). The data indicate fault activity during the last 24 kyr ago, from 20 to 24 kyr and from 24 to 37 kyr ago. The Hebgen Lake fault may be in its active state. The average displacement rate during the two active periods is about 1 m/kyr, twice as high as that calculated over the entire geological history of the fault recorded in the scarp.

# Apparent $^{36}\text{Cl}$ ages

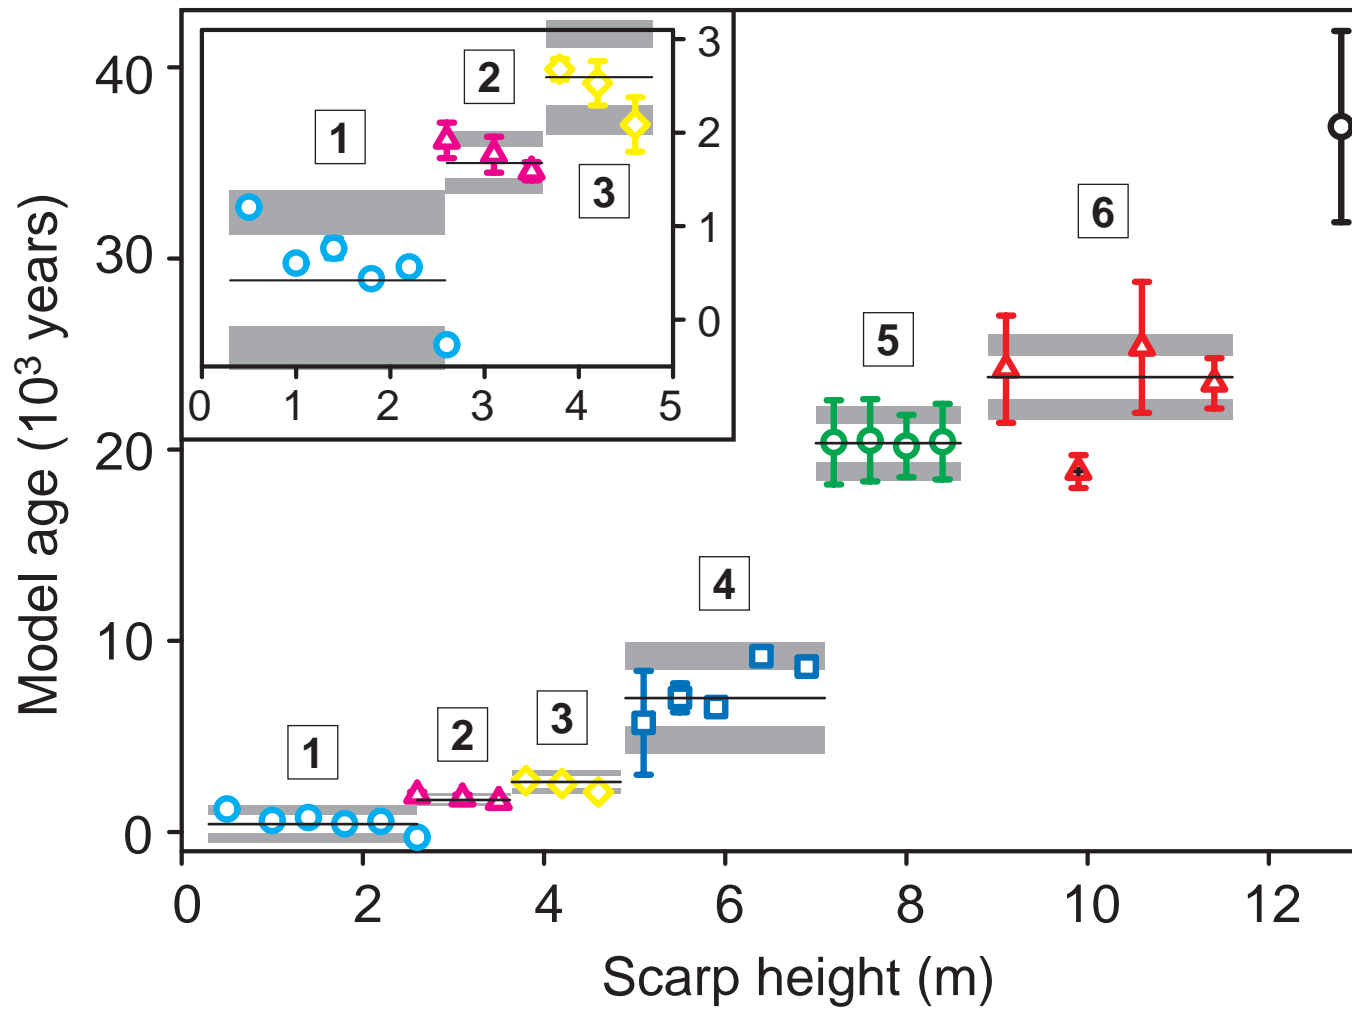

# Surface exposure ages

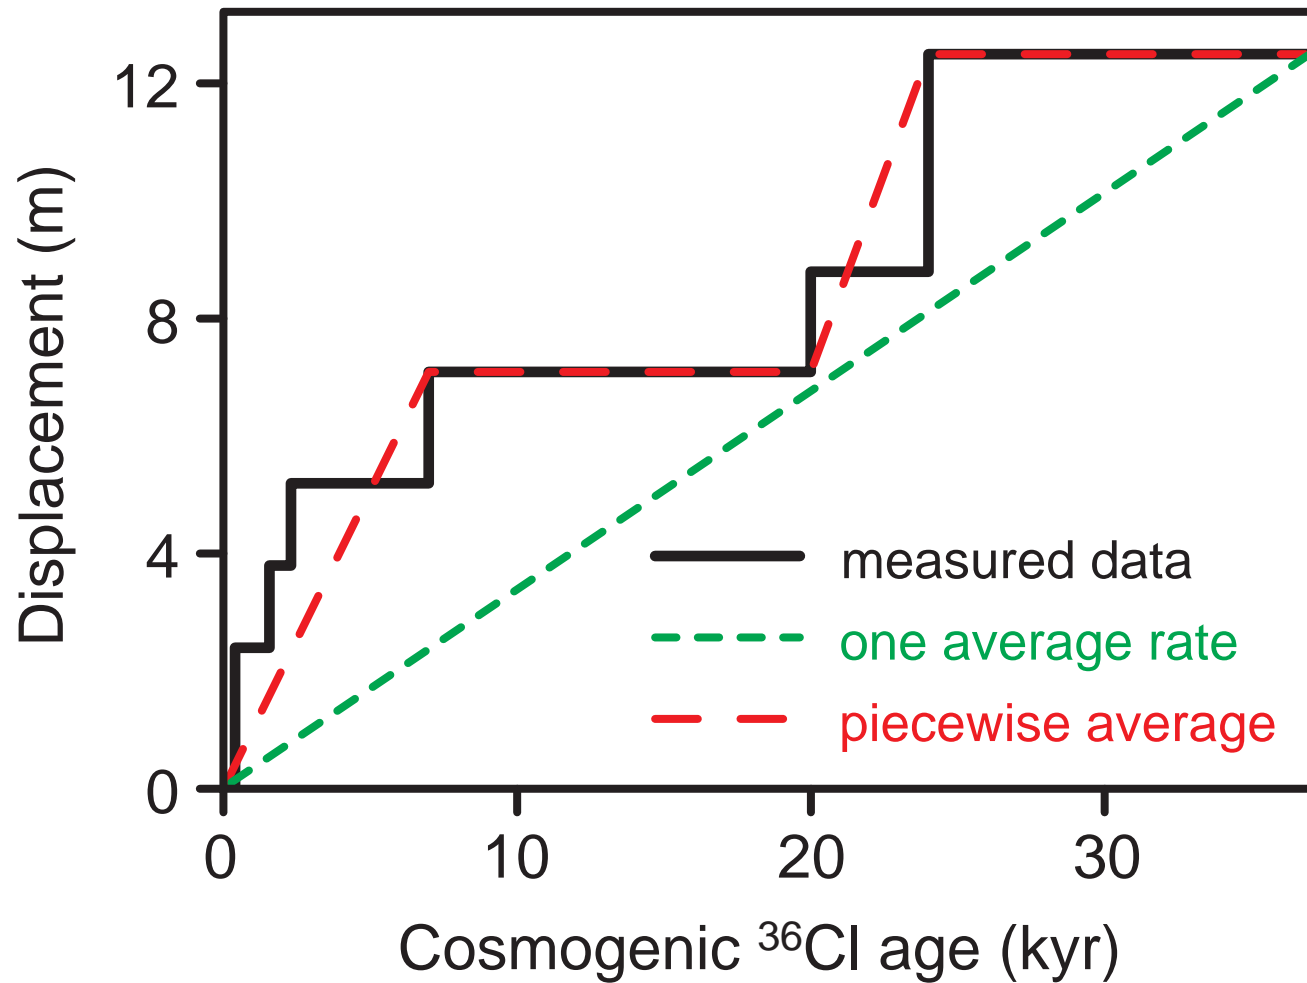

Height [m]	Age [ky]
9.1 - 11.4	23.8 ± 1.1
7.2 - 9.1	20.3 ± 1.0
5.1 - 7.2	7.0 ± 1.5
3.8 - 5.1	2.6 ± 0.3
2.6 - 3.8	1.7 ± 0.2
0.5 - 2.6	0.4 ± 0.5

# Corrected $^{36}\text{Cl}$ ages

# Temporal clustering of earthquakes

# Vertical slip rates

<b>Time [ky]</b>	<b>Slip rate [m/ky]</b>
<b>0 - 2.6</b>	<b>2.0</b>
<b>0 - 7.0</b>	<b>1.0</b>
<b>0 - 20</b>	<b>0.45</b>
<b>0 - 24</b>	<b>0.5</b>
<b>0 - 37</b>	<b>0.33</b>
<b>7.0 - 20</b>	<b>0</b>
<b>20 - 24</b>	<b>1.25</b>

# Validity of $^{36}\text{Cl}$ approach

- ◎ **Good chronology**  
 $^{36}\text{Cl}$  ages follow predicted pattern  
they are compatible with scarp degradation data
- ◎ **Reasonable displacement rates**  
comparable to recent measurements
- ◎ **Clearly-defined clusters**

## Advantages of $^{36}\text{Cl}$ approach

- ◎ **Can date previously undatable bedrock fault scarps**
- ◎ **Can obtain complete record of multiple earthquakes at single site**
- ◎ **Dating range:  $10^3$  -  $10^{5.5}$  years**
- ◎ **Dating precision and accuracy: 10-20%**

## Conclusions

**Cosmogenic  $^{36}\text{Cl}$  dating of bedrock fault scarps is feasible**

**At Hebgen Lake, earthquakes are clustered in two time intervals: 0-7 ky and 20-24 ky**

**During active periods vertical slip rate is 1-2 m/ky**

**Long-term vertical slip rate is 0.5 m/ky**
